Understanding Packages

as Jam

Packages

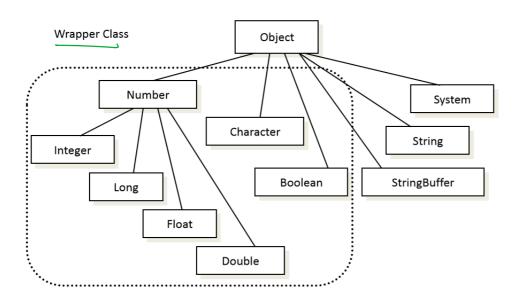

- A Package is a unique named collection of classes
- The purpose of grouping classes is to make it easy to add any or all of the classes
- Names of the classes within the package should be unique, but, same name can be repeated across the packages – as a class name is qualified with the package name

Package in Java

- A package is a namespace that organizes a set of related classes and interfaces.
- A java package is a group of related classes similar to a class library.
- Keyword 'import'
- · All of the standard classes are contained with in the packages.
- If you put multiple types in a single source file, only one can be public, and it must have the same name as the source file.
- java.lang is special

automatically imported

Package in Java

Selected packages

- java.lang -- String, wrapper classes, Math
- iava.util Calendar. Date. Vector

bike /roas bike

- java.applet Applet
- java.text DateFormat
- java.awt Graphics, Button, Label..
- javax.swing JButton
 - java.io InputStream, OutputStream

n/out, nowork

Naming Conventions

- Package names are written in all lowercase to avoid conflict with the names of classes or interfaces.
 Companies use their reversed Internet domain name to begin their package name
 - For example, com.example.orion for a package named orion created by a programmer at example.com.
- Name collisions that occur within a single company need to be handled by convention within that company, perhaps by including the region or the project name after the company name
 - (for example, com.company.region.package).
- Packages in the Java language itself begin with java. or javax.

Naming conventions

- In some cases, the internet domain name may not be a valid package name.
 - This can occur if the domain name contains a hyphen or other special character, if the package name begins with a digit or other character that is illegal to use as the beginning of a Java name, or if the package name contains a reserved Java keyword, such as "int".
 - In this event, the suggested convention is to add an underscore.
 - Ex: clipart-open.org → org.clipart_open

-mt_replace

general

Using Package Members

 The types that comprise a package are known as the package members. To use a <u>public</u> package member from outside its package, you must do one of the following:

/grap

- Refer to the member by its fully qualified name

• graphics.Rectangle myRect = new graphics.Rectangle();

Directory. filenams

Import the package member

import graphics.Rectangle;
 Rectangle myRectangle = new Rectangle();

one class from the package

- Import the member's entire package

import java.util.*;

(1)

- import graphics.*;
- import graphics.A*; //does not work

Packaging your classes

- Add a package statement as the first statement in the source file containing the class definition
- It must always be the first statement
- Ex: package geometry;

mon comment

\ keyword T necessary

//Sphere.java
package geometry;
public class Sphere
{
//westc
//details of the class definition
}

es

Packaging your classes

Directory : geometry

File: Sphere.java

 Compiling: Ensure that you are out of the directory javac /geometry/Sphere.java

/road/ Rad-gard.

protectediff []

extends hoad

Pack

package t

Sub classes outside

packag

creat

java geometry.Sphere

To execute

For a large number of files in a package you can use javac /geometry/*.java

All interdependencies will be figured out by the compiler

al files sa

Packages and directory structure

- A package is intimately related to the directory structure in which it is stored
- A class with a Classname must be stored in a file called Classname.java
- Similarly, all the files for classes within a package, packageName must be included in a directory with the name, packageName.
- A package need not have a single name. it can be a sequence of names separated by a period

package geometry.shapes3D; package geometry.shapes2D;

 shapes3D and shapes2D are sub directories of geometry directory. /geometry/sh

18h

geometry-sha

Setting classpath

- From the command prompt,
 set CLASSPATH = .;c:\MySource; c:\MyPackages
- Unless a class path is set, or set incorrectly, java will not be able to find the classes in any new packages you might create.

Adding classes from a Package to your Program

- Classes with 'public' are accessible to your program by using 'import' statement.
 - import geometry.shapes3D(*;)//includes all the classes from this package
 - '*' selects all the classes in the package
 - You can refer any public class in the package
 - If you have to add a specific class, specify explicitly like,

import geometry.shapes3D.Sphere;

- '*' can be only used to select all the classes in a package. You cannot use geometry. * to select all the packages in the directory geometry.

Encapsulation of classes into a package

- Add a class into a package two steps:
 - 1. put the name of the package at the top of your source file

```
package com.hostname.corejava;
public class Employee {
     . . .
}
```

- 2. put the files in a package into a subdirectory which matches the full package name
 - → stored in the file "Employee.java" which is stored under "somePath/com/hostname/corejava/"

Setting the class path

<u>E.q.</u>

- current classpath: order

/home/user/classdir:.:/home/user/archives/archive.jar

- to search for the ¹ class file of the com.horstmann.corejava.Employee class

first searchs in the system class files that are stored in archives in the jre/lib and jre/lib/ext directories.

If it can't find the class there it will search in the order:

- 1) /home/user/classdir/com/horstmann/corejava/Employee.class
- 2) ./com/horstmann/corejava/Employee.class
- 3) com/horstmann/corejava/Employee.class inside

javax,

/home/user/archives/archive.jar

- if found the interpreter stops searching process

Naming conventions • Package names: start with lowercase letter

- - java.util, java.net, java.io . . .
- Class names: start with uppercase letter
 - File, Math . . . ➤ E.g.
 - > avoid name conflicts with packages
 - > avoid name conflicts with standard keywords in java system
- Variable, field and method names: start with lowercase letter
 - E.g. x, out, abs ...
- Constant names: all upper case letters
 - ➤ E.g. PI ...
- Multi-word names: capitalize the first letter of each word after the first one
 - E.g. HelloWorldApp, getName ...
- Exception class names: (1) start with uppercase letter (2) end with "Exception" with normal exception and "Error" with fatal exception
 - OutOfMemoryError, FileNotFoundException E.g.
